

**OCCURRENCE OF *PULMONICOLA COCHLEOTREMA*  
(SYN. *COCHLEOTREMA COCHLEOTREMA*) (DIGENEA: OPISTHOTREMATIDAE)  
IN ANTILLEAN MANATEES (*TRICHECHUS MANATUS MANATUS*) IN BRAZIL<sup>1</sup>**

VITOR LUZ CARVALHO<sup>2,3\*</sup>, ANA CAROLINA OLIVEIRA DE MEIRELLES<sup>3</sup>, MONICA REGINA ALVES MOTTA<sup>4</sup>, DÉBORA CASTELO BRANCO DE SOUSA COLARES MAIA<sup>2</sup>, MARIA VERÔNICA MORAES CAMPOLLO<sup>5</sup> AND CLAUDIA MARIA LEAL BEVILAQUA<sup>2</sup>

**ABSTRACT** – The present work reports the first record of the trematode parasite *Pulmonicola cochleotrema* in Antillean manatee (*Trichechus manatus manatus*) in Brazil. Out of 15 necropsied manatees in the State of Ceará, the parasite was found in the nares, trachea and bronchi of four animals (two juvenile males, one juvenile female and one adult female), for a prevalence of 26.7%. The parasites were identified based on morphological features observed in the 38 collected specimens. No pathological manifestations were observed associated with the presence of the parasites in the present study. The prevalence observed in the State of Ceará and the lack of reports of this parasite species in other states of northeastern Brazil may suggest the existence of an isolated population, a higher occurrence of the intermediate host, or differences in the feeding habits of the manatees.

**RESUMO** – Este trabalho apresenta o primeiro registro do parasito trematóide *Pulmonicola cochleotrema*, em peixe-boi-marinho (*Trichechus manatus manatus*) no Brasil. De 15 peixes-bois necropsiados no Estado do Ceará, foram encontrados parasitos nas narinas, traquéias e brônquios de quatro animais (dois machos juvenis e duas fêmeas, sendo uma adulta e uma juvenil), com prevalência de 26.7%. A identificação dos parasitos foi feita com base nas características morfológicas observadas de 38 espécimes coletados. Não foram observados sinais patológicos relacionados com a presença dos parasitos no presente estudo. A prevalência observada para o Estado do Ceará e a ausência de registro deste parasito em peixes-bois-marininhos de outros Estados do Nordeste, pode sugerir a existência de uma população isolada, uma maior abundância de hospedeiros intermediários ou diferenças nos hábitos alimentares dos animais.

**KEYWORDS:** Parasites, *Pulmonicola cochleotrema*, antillean manatee, *Trichechus manatus manatus*, Brazil.

## Introduction

The order Sirenia is comprised of the essentially herbivorous aquatic mammals that inhabit shallow coastal waters, rivers and estuaries in tropical and subtropical regions (Hartman, 1979; Marsh *et al.*, 1986, Domning, 2002). In Brazil, this order is represented by two out of the four living species: the Antillean manatee (*Trichechus manatus manatus*), one of two subspecies of the West Indian manatee (*T. manatus*), and the Amazonian manatee (*Trichechus inunguis*) (IBAMA, 2001).

The Antillean manatee is considered the most threatened species of aquatic mammal in Brazil, with a discontinuous distribution along the northern and northeastern coast of the country. The main causes of mortality include previously employed hunting practices, capture in fishing nets, and the stranding of calves (Oliveira *et al.*, 1990; Parente *et al.*, 2004; Meirelles, 2008). Besides anthropogenic threats, manatees can develop many infectious (Vergara-Parente *et al.*, 2003; Bossart *et al.*, 2004; Woodruff *et al.*, 2005)

and parasitic (Blair, 1981; Dubey *et al.*, 2003) diseases that may compromise their health status and cause death (Borges, 2007). The species is classified as 'critically endangered' (*i.e.* extremely high risk of extinction in the wild within the immediate future) by the Action Plan for Aquatic Mammals of Brazil (IBAMA, 2001). Captive individuals, stranded calves and carcasses found on beaches have been the main sources of information on the biology, physiology and diseases of the Antillean manatee (D'Afonseca Neto and Vegara-Parente, 2007).

The sirenian parasitic fauna is mainly composed of protozoans and roughly 25 identified species of trematodes and nematodes, most of them exclusive to this order (Dailey, 2001; Raga *et al.*, 2002). In Brazil, *Cryptosporidium* spp. oocyst infections have been reported in Antillean and Amazonian manatees (Borges *et al.*, 2007a; b). There are reports of parasitic helminthes infecting *T. inunguis* (Mullins *et al.*, 2003<sup>7</sup>; Borges *et al.*, 2007<sup>8</sup>), but there are no documented records for *T. manatus manatus* in the country.

The objective of the present paper is to report the first occurrence of the parasite *Pulmonicola cochleotrema* (syn. *Cochleotrema cochleotrema*) in the Antillean manatee (*T. manatus*) in Brazil.

## Material and Methods

Carcasses of Antillean manatees were recovered by *Associação de Pesquisa e Preservação de Ecossistemas Aquáticos* (Aquaasis) from January 1992 to April 2008. The carcasses were transported to the Marine Mammal Rehabilitation Centre (CRMM/SESC Ceará), where necropsies and collection of biological material were carried out in fresh and moderate decomposed animals, following the recommendations of Geraci and Lounsbury (2005) and Vergara-Parente (2005a).

During these procedures, a careful search for parasites was performed in all organic systems. Nostrils, trachea, bronchi and lungs were opened and washed and the collected content was strained. Whenever possible, the digestive tract was opened, from the esophagus to the rectum, and the content was also collected and strained. The mucosae were inspected in search of adhered parasites.

The helminthes were collected, fixed and preserved in AFA (93 parts 70% alcohol, 5 parts 40% formaldehyde and 2 parts acetic acid). The age class of the infected animals was estimated by total length, based on the data published for the Florida manatee (Marmontel, 1993).

The collected material was sent to the Laboratory of Parasitology of Ceará State University (UECE), where specimens were stained by Amato's method (1985), clarified in phenol for mounting on temporary slides, and identified using an optical microscope. Measurement of the internal structures in millimeters was accomplished using Image J™ software. The character measurement range is followed in parenthesis by the mean value. The terminology used for parasite description follows Blair (1981). Prevalence (ratio between the number of infected and the number examined animals), as well as intensity (number of parasites in one host) were calculated according to Bush *et al.* (1997).

## Results

Seventeen carcasses of Antillean manatees were recovered during the study (Table 1). In two carcasses, necropsy was not viable due to the advanced stage of decomposition. Out of the 15 necropsied animals, parasites were found in the nares, trachea and bronchi of four animals (Figure 1).

The parasites presented oval bodies with 5-11mm (7.55mm) of total length and 3-7mm (4.58mm) of maximum width. They were ventrally concave and dorsally convex. The entire margin of the body contained a strong muscular fringe. We observed a ventral,

subterminal oral sucker, measuring 0.70-1.31mm (0.96mm) in diameter, with transverse opening (Figure 2). The esophagus measured 0.20-0.50mm (0.31mm). Intestinal ceca were dorsal to all other organs, sinuous, and ending near the posterior extremity. Testes were rounded, approximately similar in size, measuring 0.48-1.07mm (0.81mm) at their largest diameter (Figure 3). Ovaries were irregular, but not deeply lobated, measuring 0.35-0.74mm (0.48mm) in diameter, located to the right or to the left of the midline, and were intercecal and pretesticular. Scarce vitellaria were distributed in irregular follicles and intercecal. The uterus was intercecal, with the opening close to the male aperture. The morphological features observed led to the identification of *Pulmonicola cochleotrema* Poche 1926.

Based on this sample, prevalence of *P. cochleotrema* was 26.7% for the State of Ceará. The infection intensity was 176 for animal 02S0111/10, 20 for animals 02S0111/34 and 02S0112/38, and eight for animal 02S0112/43 (Table 1).

## Discussion

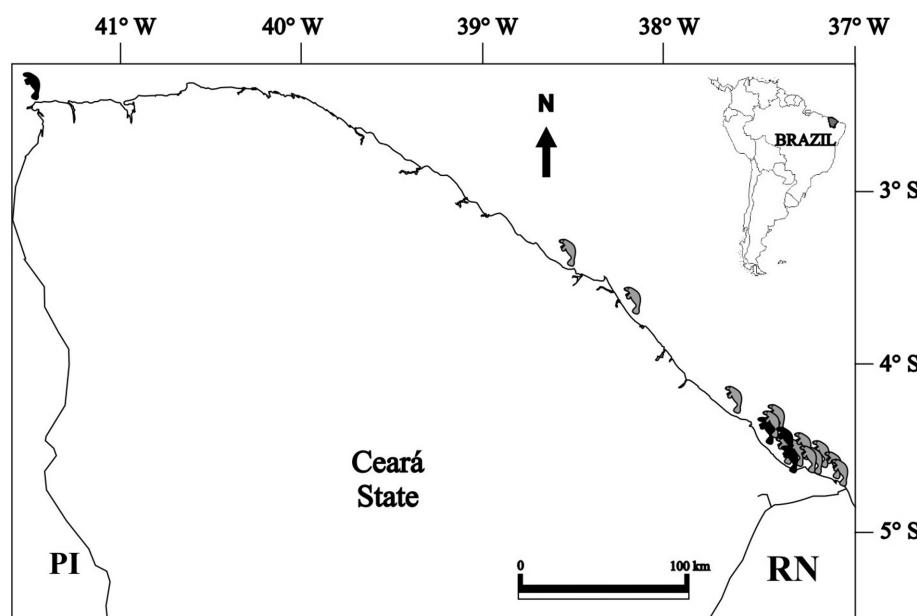

*Pulmonicola cochleotrema* is a digenetic trematode that belongs in the family Opisthotrematidae. This species is currently thought to be synonymous with *Cochleotrema cochleotrema* (Blair, 2005). It is found mainly in the nares, though it can also be found in the trachea and bronchi of manatees (Beck and Forrester, 1988). The species has been reported to parasitize *T. manatus* in the United States, Guyana, Puerto Rico, Dominican Republic, and elsewhere in the Caribbean (Beck and Forrester, 1988; Mignucci-Giannoni *et al.*, 1999). In Brazil, the only record of this parasite is in the intestine of a *T. inunguis* kept in captivity in Balbina, State of Amazonas (Mullins *et al.*, 2003<sup>a</sup>).

In the animals examined in the present study, no macroscopic pathological signs were observed related to the presence of *P. cochleotrema*. Sirenian parasites are rarely associated with clinical manifestations (Bossart, 2001). However, severe infections caused by *P. cochleotrema* have been reported in an adult Florida manatee, resulting in chronic rhinitis and pulmonary edema, and in a juvenile female, resulting in chronic ulcerative epiglottitis and parasitic pneumonia (Beck and Forrester, 1988). These findings were reported in animals that presented infection intensity of 250 and 490, respectively. Such values are greater than the ones found in the present study, where the highest intensity was 176.

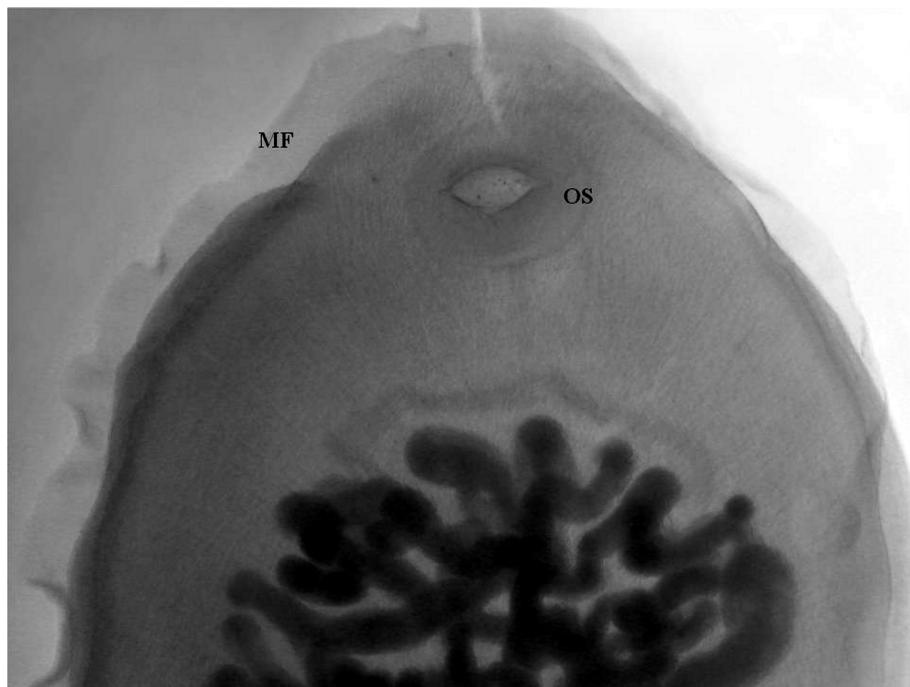

The life cycles of sirenian parasites have not been determined; however, it is thought that nematodes of sirenians may use crustaceans as intermediate hosts, which can be incidentally consumed during grazing (Jueco, 1977; Beck and Forrester, 1988). The trematode species present in sirenians likely use mollusks as intermediate hosts and are infected by the incidental ingestion of the larval stages on contaminated food plants (Blair, 1981; Beck and Forrester, 1988; Yamaguti, 1971).

**Figure 1.** Distribution of strandings of dead Antillean manatees (manatee symbols) in the State of Ceará. Black manatees indicate the presence of *Pulmonicola cochleotrema*.

**Figure 2.** Anterior portion of *Pulmonicola cochleotrema*, collected from an Antillean manatee from the State of Ceará, showing muscular fringe (MF) and oral sucker (OS), with transversal opening (10X).

**Figure 3.** Posterior portion of *Pulmonicola cochleotrema*, showing the rounded testes (T) and ovary (O) (10X).

Beck and Forrester (1988) observed that larger and older animals hosted a greater number of parasites, probably due to the larger habitat available within the host and the increased chances of exposure according to the age. Conversely, calves with less exposure time to the infective stages also consume less vegetation than the older animals.

In the present study, the infected manatees were two juvenile males, one juvenile female and one adult female. Despite the small number of samples, the

findings are compatible with Beck and Forrester (1988), considering that 35.3% of the animals necropsied in their study were calves and no parasites were observed in these specimens.

Despite ongoing research efforts, the presence of helminthes has not been previously reported in *T. manatus* in Brazil. The Projeto Peixe-Boi/ICMBio has monitored the occurrence of gastrointestinal helminthosis in Antillean manatees kept in captivity since 1991, and none of the samples collected and

examined during necropsies have contained eggs, larva or adult of *any* parasite species (Vergara-Parente, 2005b). Beck and Forrester (1988) reported differences in the prevalence of *P. cochleotrema* from different locations in Florida; however, it was not known if this reflected a variation in the distribution or abundance of definitive and intermediate hosts, or variations in the habitat, such as water salinity, temperature and other factors. The prevalence of 26.7% of *P. cochleotrema* in the State of Ceará may suggest the existence of an isolated population of this parasite, a greater abundance of intermediate hosts or differences in the feeding habits of the manatees. It is important to emphasize that occurrence and intensity may be underestimated since these parasites can be easily lost from the nares in the carcasses when they are in the water or during transport (Beck and Forrester, 1988). Moreover, the largest research effort in recent years may have contributed to underestimate prevalence, since the parasites were found during the period when collection protocols have been improved.

Many parasites are used as natural markers of biological and environmental phenomena because their transmission is closely related to host and environmental characteristics. They can be used as biological indicators of phylogeny, local migration, distribution, disease, stock identity and social behavior (Geraci and Lounsbury, 2002). However, in this study, the number of evaluated animals from the location where the infection was diagnosed is insufficient for the utilization of *P. cochleotrema* as a biological marker. Thus, further study is necessary to determine whether *P. cochleotrema* infection can be used in this way. Increased research efforts, improvement of parasite collection protocols, training of specialized personnel and investigation of food content of animals from different locations will facilitate this process. The increasing threats to the manatees and the reduced number of individuals present on the Brazilian coast make research on this species of great importance for their conservation, including the detection of parasitic agents.

## Acknowledgements

We thank João Carlos Gomes Borges, Jociery Einhardt Vergara-Parente, Fernanda Menezes de Oliveira e Silva and Cristine Pereira Negrão Silva for their reviews and important suggestions; the Aquasis team, for their work recovering and performing manatees necropsies; Dr. Cláudio Cabral Campello for contributions in preparing the photographs; Dr. Cathy Beck and other referees for their comments and suggestions to improve this manuscript; and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support.
